TR－1－0044
Record of Six Work Sessions on
Concepis，Methods，and Tools from Existing Running Real－Size MT Systems

ワークセッション記録：<br>MTシステムの概念，手法，ツール

Christian Boitet
クリスチャン・ブワテ

October， 1988

## Foreword

This is a record of six work sessions organized by Professor Christian Boitet during his stay at ATR.

Using his long research experience in the field of Machine Translation, Professor Boitet reviewed the concepts, methods, and tools of existing or previously running real-size MT systems. He discussed them with the ATR researchers in order to work out the "best set" of principles for an Automatic Interpretation System, taking into account existing dangers, illusions, and solutions.

He prepared more than a hundred transparent sheets for the work sessions, which are the main sources of this record. However, some errors might have occured in the editing process of the hand-written transparent sheets into this typed format. I would like to apologize to the author for the remaining errors.
(T. Aizawa)

# Six Work Sessions on Concepts, Methods, and Tools from Existing Running Real-Size MT Systems

Unified architecture rather than accidental pasting

## INTRODUCTION

Why refer to MT (Machine Translation) systems if we attack MI (Machine Interpretation) systems?

- Prof. Nagao's warning not to follow MT design blindly
- Written \& spoken language, translation \& interpetation:

A common basis

- Research in NLP as a finite-state device much has been done .....
..... and forgotten
- Usual scientific practice to build on accumulated knowledge .....
..... without rediscovering the wheel
- B. Vauquois' contribution \& evolution;
- Coincidental with the history of modern MT
- Illustrates the bychological side

## Historical Perspective

## Outline of Presentations

A. Through a retracing of B.Vauquois' contribution \& evolution

1. The researcher \& hisideas

1960~65 Applying formal language theory
1965~70 Integrating modern semantic theories
1970~75 Defining modular grammars and heuristic methods
1975~80 Inventing multilevel (M-)Structures
1980~85 "Static grammars" for specifying the string-tree correspondences
1985~ Towards a new treatment of ambiguity
2. The implementer \& his methods

Erudition, eclectism \& pragmatism in linguistics specialized languages adapted to the tasks emergence of lingware engineering methods
B. With a rapid survey of some MT systems

1. SYSTRAN \& variants
2. CETA \& METAL
3. SUSY \& LOGOS
4. METEO \& TAUM-AVIATION
5. ARIANE- 78 \& -85
6. Japanese systems
7. EUROTRA ?
C. A summary of the important issues
```
Grammar in CNF
    \(A \rightarrow B C\)
    \(A \rightarrow t\)
With attributes on symbols
    - Normal (gender, number .....)
    - "Vehicular" (for discontinuines)
And validations/saturations on rules
\[
\begin{aligned}
\mathrm{R}_{\mathrm{A} 1}: \quad \mathrm{A} \rightarrow \mathrm{BC} & / P(\mathrm{~A}(\mathrm{~B}), a(\mathrm{C})) \\
& 1 \alpha(\mathrm{~A}):=\mathrm{F}(\mathrm{a}(\mathrm{~B}), \alpha(\mathrm{C})) \\
& 1-\left(\mathrm{R}_{\mathrm{i}}, \mathrm{R}_{j}, \ldots \ldots\right),+\left(\mathrm{R}_{\mathrm{r}}, \ldots . .\right) .
\end{aligned}
\]
```

## Cocke algorithm

with some improvements.

1965~70 Integrating modern semantic theories

- Need for a "PIVOT",

More universal than binary attributed phrase-structures

- Ideas from

Tesnière: Actants
Mel'čuk : Meaning-text
Šaumjan: Hybrid pivot

- Necessity to

Select one binary structure
transform it into PIVOT form

## The PIVOT

A "universal" structure (grammatical \& relational symbols) with a languagedependentlexicon.

John convinced him to go using charm

## Selection of initial structure and obtention of PIVOT structure

- Preference rules
(For same covered substring)
Notimplemented yet as metalanguage
- Transformation into an initial

Dependency structure

$$
\mathrm{A} \rightarrow \mathrm{BC} /-/-/ \mathrm{B}
$$

- Then, transformations expressed in a special metalanguage

## 1970~75 Defining modular grammars \& heuristic methods

- Intractability of big rule systems for human control Still applicable today
- Difficulty in expressing preferences
- Belief that direct methods based on heuristics would be quicker \& more adequate.
$\Rightarrow \quad$ Analysis in ARIANE-78
Morphology : $\quad \begin{aligned} & \text { Combinatorial \& Heuristics } \\ & \text { (ATEF) }\end{aligned}$
Syntax/Semantics : Procedural \& Heuristics (ROBRA)

## ATEF

- Computation: ND/*/Depth-first \& Heuristics

- Pruning of search tree
- Possibility to suppress previous, tentative results.

> inputstring

- Output : Factorizing tree

Time flies like an arrow

## ROBRA

Tree-transformational systems

- Control graph
- Ordered grammars on nodes
- Conditions on the arcs
- ND / 1/ Depth first
\& Context-senstive rules (on trees)
Recursive calls
Parallel application of rules
Guarded iteration \& recursion

See GRADE for comparison.

1975~80 Inventing multilevel (M-)Structures

- Layers of interpretation levels

| Syntactic categories | CAT | Words |
| :--- | :--- | :--- |
|  | K | Clauses |

Syntactic functions SUBJ
OBJ1
OBJ2
Slightly different ATROBJ
From dependency CPAG
Relations which relate only words, not words / groups with words / groups.

Logical argument places
ARGO
ARG1
ARG2
TRL01
TRL12

| Semantic relations | INSTR | AGENT |
| :--- | :--- | :--- |
|  | CAUSE | "TOY" |
|  | ACCOMP | LOCAL |
|  | MEASURE | CONSEQ |
|  | QFIER |  |
|  | QFIED |  |

- Other levels

Actualisation Time/Mode / Aspect
Discourse type Quest/Indir/Cmd.....
Theme/Rheme - Notimplemented yet
Sem.features Concr, Abstr, Docum,Presfied, Animate, Human, .....

+ Lexical units (Sem. derivational families)

## Considering M-structures as implicit generators of other structures

- Classical

$$
\begin{aligned}
\mathrm{C}- & \\
\mathrm{F}- & \text { Structures } \\
\text { SPA- } &
\end{aligned}
$$

- Alternate structures:

Encoding Ambiguities
Doubts
\& During transfer
Encoding Advices or Orders
To the generator

- At the beginning of generation, 1 structure encodes all paraphrases legitimate (For translation)

Usually, but not necessarily, lexical units are not changed during generation.

1980~85 Specifying string-tree correspondences by static grammars

- Necessity of specification formalism, in view of the size of the (procedural) grammars, even if modular.
- Used in practice since 1983 (national project)
- A small example on a formal language (using a simplified syntax)

$$
\left(\begin{array}{cccccc}
a_{1} & a_{2} & b_{1} & b_{2} & c_{1} & c_{2}
\end{array}\right) \quad \text { String }
$$

By the following derivation

See some analogy with XYZGs ... . But in Zaharin-86, Unification -Identification.

$$
\begin{aligned}
& \text { R1: }\left(\begin{array}{cc}
a b c \\
& L_{i} \\
a & b \\
a
\end{array}\right) \rightarrow\binom{a}{a}\left(\begin{array}{l}
b \\
a \\
b
\end{array}\right)\left(\begin{array}{l}
c \\
c \\
c
\end{array}\right)
\end{aligned}
$$

## 1985~ Toward a new treatment of ambiguity

- In practice, "static grammars" also contain (up to 75\%!) preference rules

(In procedural analysis grammar, if T 1 is chosen, T 2 may be encoded.)
- Desire to treat ambiguities directly at the level of the final description of the linguistic computation
- Open area, research theme
- Somewhat analogous to more ancient techniques, but in the spirit of today's "expert systems".

## The implementor \& his methods

Erudition, eclectism, pragmatism in linguistics

- Not a blind follower of some ideology ("Mainstream" or other)
- No linguistic theory actually covers more than a fraction of the linguistic facts/phenomena.
- Good ideas may come from different sources

Theoreticians and grammarians

- Theories \& usually accepted concept are sometime inexact and must be corrected/improved.

Specialized languages for linguistic programming adapted to the various tasks

- No unique computational

Framework is good for everything
Very general SLLPs tend to be very inefficient for specific tasks such
as morphology
Maybe a useful consideration also in the case of MI systems.

- Building SLLPs on subrecursive formalisms, with the possibility
- To allow for some "liberty switches" static detection
- To evaluate the order of complexity of the associated computations.

## The emergence of lingware engineering

- "Lingware" coined at GETA to reflect the parallelism with software engineering.
- Development \& maintenance problems

Some figures derived from CAT-NP quite in accordance with B.
Vauquois' estimates.

- From all points of view

Linguistics (Content: Grammar/Lexicons)
Computer science
Formalisms \& mathematics
Building MT systems necessitates to fix the state of the art at some point
$\Rightarrow$ Success of METAL
Failure of eternal prototyping / EUROTRA)

## Basic Architectures and Concepts

## A rapid survey of real-size MT systems

## SYSTRAN \& Variants

Fixed flow of control
No possibility to backtrack or process several solutions in parallel
No explicit grammar rules
No .....
But

Enormous amount of work put in dictionaries
Experience on extremely large corpuses
Incredible speed
Usable for

- information-gathering in general
- translation, in very specific settings (XEROX .....)

## CETA \& METAL

- Comparable in computational technique
- All-path of analysis
- Attached transformations for analysis
- Big dictionaries

But some differences
Preference rules / Weights
Hybrid PIVOT / Hybrid transfer ( $\mathrm{T}+\mathrm{G}$ mixed)
Dependency structures / Constituentstructures
All-or-nothing / Fail-soft Implementation of the SLLPs
Assembler
/ Lisp

- CETA faster (80000 ipw / 1.5 Mopw)
- METAL (1981~86) 15 years later, more usable \& up-to-date
- Becase ceta model was much more theory-oriented .....? $\rightarrow$ Discussion!

## SUSY \& LOGOS

- Both ~ 1.5 generation:

SLLP for dictionaries, not for grammars
$\rightarrow$ Difficult to adapt the grammars

- Both usable (LOGOS commercially, SUSY exper. at IAI)
- Both relying on combinatorial approach for analysis
- Both unclear linguistically \& computationally

Structures manipulated \& produced not independently defined, but in terms of the implementation.

- Both, but LOGOS even more, give great emphasis on dictionarybuilding facilities.

## METEO \& TAUM-Aviation

- METEO
Q-systems (A. Colmerauer)
$95 \%$ quality since 1983

In 1985, switched to fail-safe approach
1988: $120 \mathrm{w} / \mathrm{mn}$ on a lap top
300,000 pages translated since $1977 \quad(\sim 100$ p/day $)$
(or $25,000 \mathrm{w} / \mathrm{day}$ )

Sematics-based analysis
(Categories such as "Meteorological Event")
Q-systems: General "Addition"
Production system (on Q-graph)

- All rules apply on all possible occurrences; arcs used in L.H.S. are marked.
- If \& when application stops, marked arcs \& "loose ends" are erased; another Q-graph is output.

## $\{\mathrm{AnBnCn} \mid \mathrm{n} \geqq 1\}$ in Q-Systems

Input: $\quad-01-\mathrm{A}+\mathrm{A}+\mathrm{A}+\mathrm{B}+\mathrm{B}+\mathrm{B}+\mathrm{C}+\mathrm{C}+\mathrm{C}-02-$

G1) Parameter-Free

$$
\mathrm{A}+\mathrm{B}+\mathrm{C}==\mathrm{S}
$$

$$
\mathrm{A}+\mathrm{S}+\mathrm{B}\left(^{*}\right)+\mathrm{C}==\mathrm{S}
$$

$$
\begin{array}{ll}
\mathrm{B}+\mathrm{B} & ==\mathrm{B}+\mathrm{B}\left(^{*}\right) \\
\mathrm{B}\left(^{*}\right)+\mathrm{C} & ==\mathrm{C}+\mathrm{B}\left(^{*}\right)
\end{array}
$$

Q-Grammar

$$
\left(\begin{array}{ll}
\mathrm{B}(*) \equiv & \left.\begin{array}{l}
\mathrm{B} \\
*
\end{array}\right)
\end{array}\right)
$$

(G2) Counting Q-Grammar (Output $=\mathrm{S}(1 \mathrm{n})$ )

$$
\begin{aligned}
\mathrm{A}+\mathrm{B}+\mathrm{C} & ==\mathrm{S}(\mathrm{I}) \\
\mathrm{A}+\mathrm{S}\left(\mathrm{U}^{*}\right)+\mathrm{B}\left({ }^{*}\right)+\mathrm{C} & ==\mathrm{S}\left(\mathrm{I}, \mathrm{U}^{*}\right) \\
\mathrm{B}+\mathrm{B} & = \\
\mathrm{B}\left(^{*}\right)+\mathrm{C} & =\mathrm{B}+\mathrm{B}\left(^{*}\right) \\
& =\mathrm{C}+\mathrm{B}\left(^{*}\right)
\end{aligned} \quad * * \mathrm{U}^{*} \text { is a list. }
$$

Also reversible
(produce AnBnCn from $\mathrm{S}(1 \mathrm{n})$ ).

G3) Structuring Q-Grammar (Output $=\mathrm{S}\left(\mathrm{A}_{1}, \mathrm{~B}_{1}, \mathrm{C}_{1}, \mathrm{~S}(\ldots .).\right)$ )

$$
\begin{array}{r}
\mathrm{A}^{*}+\mathrm{B}^{*} \quad==\mathrm{S}\left(\mathrm{~A}^{*}, \mathrm{~B}^{*}\right) / \mathrm{A}^{*}-\mathrm{IN}-\$ \$ \mathrm{ABC}-\mathrm{AND}-\mathrm{B}^{*}-\mathrm{IN}-\$ \$ \mathrm{ABC} \\
\mathrm{~A}^{*}+\mathrm{S}\left(\mathrm{U}^{*}\right)=\mathrm{S}\left(\mathrm{~A}^{*}, \mathrm{U}^{*}\right) / \mathrm{A}^{*}-\mathrm{IN}-\mathrm{A}, \mathrm{~B}, \mathrm{C} \\
-\mathrm{REQ}-\quad \mathrm{HERE},-01-\mathrm{S}\left(\mathrm{~A}_{1}, \mathrm{~A}_{2} \ldots \mathrm{~A}_{\mathrm{n}}, \mathrm{~B}_{1}, \ldots \mathrm{~B}_{\mathrm{n}}, \mathrm{C}_{1}, \ldots \mathrm{C}_{\mathrm{n}}\right) \\
\mathrm{S}\left(\mathrm{U}^{*}, \mathrm{~A}, \mathrm{~V}^{*}, \mathrm{~B}, \mathrm{~W}^{*}, \mathrm{C}\right)==\mathrm{S}\left(\mathrm{U}^{*}, \mathrm{~V}^{*}, \mathrm{~W}^{*}, \mathrm{~S}(\mathrm{~A}, \mathrm{~B}, \mathrm{C})\right) / \mathrm{U}^{*}-\mathrm{IN}-\mathrm{A}-\mathrm{AND-} \\
\mathrm{~V}^{*}-\mathrm{IN}-\mathrm{B}-\mathrm{AND}- \\
\mathrm{W}^{*}-\mathrm{IN}-\mathrm{C} \\
\mathrm{~S}\left(\mathrm{U}^{*}, \mathrm{~A}, \mathrm{~V}^{*}, \mathrm{~B}, \mathrm{~W}^{*}, \mathrm{C}, \mathrm{~S}\left(\mathrm{X}^{*}\right)\right)==\mathrm{S}\left(\mathrm{U}^{*}, \mathrm{~V}^{*}, \mathrm{~W}^{*}, \mathrm{~S}\left(\mathrm{~A}, \mathrm{~B}, \mathrm{C}, \mathrm{~S}\left(\mathrm{X}^{*}\right)\right)\right) /--. \\
\text { Also reversible (produce AnBnCn} \\
\text { from } \mathrm{S}(\mathrm{~A}, \mathrm{~B}, \mathrm{C}, \mathrm{~S}(\mathrm{~A}, \mathrm{~B}, \mathrm{C}, \mathrm{~S}(\ldots . ., \mathrm{S}(\mathrm{~A}, \mathrm{~B}, \mathrm{C}))))) .
\end{array}
$$

TAUM-Aviation (1976/77~1981)

- Aim at large sublanguage
(Maintenance manuals for aircraft)
- Several SLLP's

Q-systems (Generation \& 1st version of morph. an.)
REZO (ATN-like transducers of R-graphs binary features added)
LEXTRA (Lexical transfer + transformational rules)

- All or nothing approach (Acceptor-based) $\rightarrow$ High quality

But failure (1981)
Main reason:
Dictionaries (transfer) too costly because of complex transformations
Also:
ATNs bad for large grammars
(Delicate heuristics \& "PATCH-UPs")
Too detailed semantic feaures
$\rightarrow$ increase in cost
$\rightarrow$ decrease in adaptability

## ARIANE-78 \& 85

- In both, structural analysis using tree-transducer (in ROBRA)
- Pattern-matching facilitates heuristic programming, but decreases speed ( $\sim \times 40$ )
- Dictionary aspect not strong enough in Ariane-78:
$\rightarrow$ Improvements in ARIANE-85 ("Lexical expansion" optional phases)
$\rightarrow$ External "neutral" lexical data base + support utilities (CAT-NP)
- Some combinatorial step could be added to reduce ambiguities before structural analysis.
- However, tree-transducer gives more flexibility than attached transformations or ATN-like mechanism.
$\left\{\mathrm{AnBn}^{\mathrm{Cn}} \mid \mathrm{n} \geqq 1\right\}$ in ROBRA

Input $\quad: \quad \mathrm{X}\left(\mathrm{A}_{1}, \ldots . ., \mathrm{A}_{\mathrm{n}}, \mathrm{B}_{1}, \ldots ., \mathrm{B}_{\mathrm{n}}, \mathrm{C}_{1}, \ldots . ., \mathrm{C}_{\mathrm{n}}\right)$
Control Graph :

(Slightly simplified syntax)

```
G(\underline{H}): R1(G/R2,R3 / X (Y))
Search R2(G/R2,R3/\underline{X}(\underline{Y}))
from R3;
"High" to
"Low"
```

"Validated Nodes" during guarded recursion

```
\(R 1\) : X\&R(\$U, A, \$V,B,\$W,C,*) / A:'A';B:'B’;C:'C';
```

right $==\underline{X}(\$ \mathrm{U}, \$ \mathrm{~V}, \$ \mathrm{~W}, \underline{\mathrm{Y}}(\mathrm{A}, \mathrm{B}, \mathrm{C})) / / \mathrm{Y}: / \mathrm{S} ’ ; \mathrm{X}: ‘ \mathrm{~S} ’$.
** May be added, tree is :

R2: (LEVEL = 1) X \& R(\$U, A, \$V, B, \$W, C, Z, *) / .....; X: 'S' ; Z : 'S’

$$
==\underline{X}(\$ \mathrm{U}, \$ \mathrm{~V}, \$ \mathrm{~W}, \underline{\mathrm{Y}}(\mathrm{~A}, \mathrm{~B}, \mathrm{C}, \mathrm{Z})) / / \mathrm{Y}: ‘ \mathrm{~S}^{\prime} .
$$

** Succeeds at the end when tree is:

$\mathrm{R} 3:(\mathrm{LEVEL}=0) \quad \mathrm{X}(*, \mathrm{Y}, *) / \mathrm{X}=\mathrm{Y}=' \mathrm{~S} '$

$$
==Y
$$

Japanese Systems

- Pivot

FUJITSU , NEC

- Dictionaries (Large)

Direct
Neutral
Conceptual
Enormous work, perhaps multiplied if pivot ( $\rightarrow$ sort of normalization across languages).

## Summary of some important points in MT (of written texts)

Basic architecture \& concepts

- The external characteristics for decision-makers
- Linked with intended use/evolution

Representation of the units of translation
..... And what they are (sentences, paragraphs .....)
$¿$ Can developers understand them?
Specification / application of grammars \& dict.
The declarative/procedural
Competence / performance Controversy
Specialized languages for linguistic programming
A classification by the cost of running
Comparable applications
Organization of the whole MT system
The importance of size
Various environments necessary (tests, debugging, prod.)
How to achieve modularity at user-lever (lingware / texts)

External characteristics seen by potential users (interested in technique)

- Basic architecture \& concepts
(1) Direct

Transfer
Pivot
(2) Structure of grammar / dictionaries

Explicit / Buriedin codes
Modular / Bigblock
$\longrightarrow$ Domain
Typology
Expert knowledge available?
Mixed with linguistic Knowledge. (TAUM-METEO)
Separated ("coupling" $2 \mathrm{G}+\mathrm{KB}$ )
Integrated by compilation (CMU)
(3) Treatment of ambiguities

Combinatorial / Heuristic / ..... None
Batch / Interactive

# Representation of the Units of Translation 

- In existing MT systems

Computer structures
Linguistic content/interpretation
Dubious / incomplete / ambiguous analysis

- What about (unmentioned) F-structures?

Derivation trees vs. representation trees
Geometry (lists) vs. Algebra (sets)
Keep (attributed) trees with F-structures, if any (\& why not?)

- A sketch of the beginning of a tentative approach for a convenient RS for MIS Some motivations
Levels of description, contents of cells
Open problems (\& possibilities)

## More Internal Characteristics

- Representation of the units of translation
(1) Computer structures

Strings
Lattices / charts
Labelled / decorated / "featured" trees
General graphs/semantic networks
Logical formulae
More "AI" oriented
$\pm$ Encoding of ambiguity $\rightarrow$ important for MT
(2) Linguistic content

Levels of interpretation (CAT/K, SF, LR, SR)
Grammatical properties
Actualisation, determination, quantification

> Semantic features / restrictions
> Discourse-related (theme, emphasis, .....)
(3) Representation of ambiguity /doubt.....
$\pm$ Encoding of strategic indications for later processing

## What Units of Translation?

- In all systems but GETA's, sentence by sentence
$\rightarrow$ Quite empty talk about anaphora resolution, discourse structure, etc.
- AtTAUM (~1972-73), some experiments with "transferring" to next .....
$\rightarrow$ Notquite useful
- In GETA's systems, ( $\sim 1 / 2$ page or more), still
$\rightarrow$ Only used for intersentential anaphora, sentence splitting / joining
$\rightarrow$ Not enough linguistic knowledge for really more discourse-related proc.
$\rightarrow$ Long term memory needed e.g. definition of acronyms at beginning
- In MIS? One can suggest

Current complete utterance + All past dialogue

+ Abstractions (SPK, TOPIC)

Here, we center on the representation of the current occurrence

Anyway, a decomposition in paragraph-like units seems reasonable. Then use previous limit.

| 2 | Input or output representations |
| :---: | :---: |
| K | "Interface Structures" |
| I |  |
| N | Internal representations |
| D | "Working Structures" |
| S |  |

Hierarchy may be implicit ( $\rightarrow$ Prop. list)
CAT. : exc ( $\mathrm{N}, \mathrm{A}, \ldots .$. )
SUBN : nex (CN, PN)
SUBA: nex (ADV, ADJ)

## Trees

Labelled

Problem : Algebraic information mixed with the geometric structure

Attributed
(Binary features)

Node: ‘CITY' - [ SG, CONCR, ABSTR, N, ..... ]
Label
Features

Decorated
(Typed attributes)

Node: 'NP' - [ NB (SG), SEM (CONCR, ABSTR), HEAD ('CITY')]

Many systems (incl. SUSY, GETA, SALAT-Heidelberg .....)
Use the label to express:

- The "Main category" on non-terminals
- The "Lexical reference" on terminals

## Charts / Q-Graphs

Charts (KAY, MIND system, ~1965)
Loop-free graph with linear basis

Q-graphs (Colmerauer, Q-systems, 1970)
园

$$
\begin{array}{rll}
\text { Objects : } & \text { Labelled Trees } & \text { (Q-system) } \\

| Output Text | $\sim$ ALL |  |  |  |  |  |  |  |  | $\begin{aligned} & \text { METEO } \\ & \text { T.AVIA } \\ & \text { (1 part.) } \end{aligned}$ |  |  |  |

Linguistic "Content" (rather, "INTERPRETATION")

| Derivation tree | $/$ Representation tree |
| :---: | :---: |
| Grammar bound | Language bound |
| $\sim$ Always projective | Independently defined |
|  | Better for MT |
|  | (As for Compilers) |

Lexical Information

- Lemmas
- Lexical Units

MOVE / MOVER / MOTION / MOVABLE
$1 \mathrm{LU}=1$ Derivational Family (MOR / SYN / SEM)
Several Meaning Subfamilies
(OBSERVE / OBSERVANCE)
(OBSERVE / OBSERVATION)

Lexical Functions (à la Mel'chuk)
Not (yet) used in MT [Power]
Lexical units give good (translational) paraphrasing

+ Annex INFO - Valencies / Case Frames
- Semantic Features

Grammatical Information

- Morphosyntactic Info (Gender, Number, Category ...)
- Determination
- Actualization (Tense / Mode / Aspect .....)
- Syntagmatic Category (1st "Level of Interpretation")

## Relational Information

SF Syntactic Function
(More than dependency relation, because relates a word or a group of words to same.)

LR Logical Relation
(ARGO, ARG1, ARG2, ARG12, TRL10, TRL21, .....)
SR Semantic Relation
(CAUSE, INSTR, CONSEQ, MEASURE, ACCOMP, LOCAL, TOY, DEST, ORIGIN, .....)

SR $\neq \mathrm{LR}$
SR difficult to compute on arguments
For translation of arguments, LR is enough ( + SEM features).

| A Key ${ }^{\text {INStr }}$ | Opens | a Door ${ }^{\text {TOY }}$ |  |
| :---: | :---: | :---: | :---: |
| One ${ }^{\text {agnt }}$ | Opens | a Door ${ }^{\text {TOY }}$ | With a Key ${ }^{\text {INST }}$ |
| ADOOR ${ }^{2}$ | Opens |  | (With a Key ${ }^{\text {INST }}$ ) |
| ARGO | PRED | ARGI |  |

Levels of Interpretation in Interface Source Structures

O Used for analysis but not in interface structure

## Dubious / Incomplete / Ambiguous Analysis

- Almost all systems choose a "Disambiguated" solution, thereby losing the ability to
- Transfer the Doubt/Ambiguity
- Treat these phenomena
- Pr. Vauquois' Solution

Use Interface Structures as Objects, \& Encode

- Marks of Doubt
- Some Ambiguities/Polysemies
- Indications for later processing

## Examples

Ambiguity
Doubt
AMBIG (SUJOBT)
DOUBT (STRUCT)
RL(-)
FS(-)
K (PHVB)

Which writer cites this speaker?
It is best to cook it in the oven.
RS (LOC)
DOUBT (RS) INSTR ?

For each type of problem, each application defines
the default chosen, and the encoding of alternatives.

What about still ummentioned Feature-Structures (complex DAGs)?

- 2 Extremes
(1) Simply labelled representation trees
(2) Complex F-Structures on binary derivation trees
$1 \rightarrow$ Clumsy handling of set operations or predicates
$2 \rightarrow$ Clumsy handling of sequences
(Order, Repetitions, .....)
- Decorated Trees more "Balanced"
- Each node has bounded-size Info
- Natural encoding of set/sequence related Infos
- But Complex F-Structures more explicit
(Actually, too much for intensive computation:
Reentrancy impedes "Divide \& Conquer")

## A Simple Example

$$
\begin{array}{ll}
\mathrm{E} \rightarrow \mathrm{E}+\mathrm{T} /+(\alpha 1, \alpha 3) \\
\mathrm{E} \rightarrow \mathrm{~T} & / \alpha 1 \\
\mathrm{~T} \rightarrow \mathrm{~T}^{*} \mathrm{~F} & / *(\alpha 1, \alpha 3) \\
\mathrm{T} \rightarrow \mathrm{~F} & / \alpha 1 \\
\mathrm{~F} \rightarrow(\mathrm{E}) & / a 2 \\
\mathrm{~F} \rightarrow \underline{\text { id }} & / \underline{\text { id }}
\end{array}
$$

Linguistic representations
18 Nodes should be also be

- Economical
- Conspicuous

However, there are
2 more conflicting goals :

- BeData-Bound
"Don't loose anything"
Here --. How many brackets?
- Be Goal-Bound
"Fit for Sematic Processing / Integration"

## A "Rule of Thumb" for using this or that Structure

Of course, some simple Representation Trees / F-Structures may be obtained from Derivation Trees by local attached actions.

But interesting Representation Trees (e.g. $a^{n} b^{n} c^{n}$ ) usually can not be obtained without a more Complex Device.

## A Sketch of the Beginning of a Tentative Approach

## To Define a Convenient Interface Representation Structure in a MI System

## Some Motivations

- The main problem of MI is to link speech \& NL techniques.
- Symbolic \& heuristic approaches have failed in speech processing, while stochastic methods, more "Brute-Force" are (now) doing better.
- The integration through a "Blackboard" seems a good idea, if programmed heuristics (Agenda, .....) are replaced by more parallel, weight-manipulating methods.
- The next problem of MI is basic speed.
$\rightarrow$ Impossibility of using combinatorial approaches with heavy pattern-matching or unification.

## Some Ideas

- Use a working (factorizing) structure all the way through analysis (Blackboard-Like)
- Work by levels, in the way of speech techniques.
- Construct simple structures first, and more elaborate ones on / from the simple ones which get high grades.
- Use vertical activation / lateral inhibition.

## A Possible Macroscopic View

## Content of a Cell

- Main Label \& Connexions (?) may be built in the data structure. (Not the words, however)
- Simple Attribute Structure (Or direct link to microfeatures)
- Node of Representation Tree
- With a Complex Decoration
- With the correspondences to input (SNODE, STREE)
- \& ..... with Complex F-Structure, if needed \& computable in real time.

# Specification and Application of Grammars and Dictionaries 

## Outline of Presentations

Grammars \& Dictionaries
Static / Dynamic
General / Specific (to MT) but Neutral
/ Specialized (System, Phase)
\& their writers

Main Computational Methods in NU
Combinatorial / Heuristic
Pure / Impure
How to reconcile the 2 main trends?

- Impossibility of deriving automatically an efficient program from a functional or relational specification.
- Techniques from COMP SC : Invariants
- Techniques from AI : Specific Heuristics

A Suggestion for MI Systems
From Data-Bound to Goal-Bound
\&
From Combinatorial to Heuristic

## Grammars \& Dictionaries

- Static / Dynamic

Declarative + Procedural

- General / ....
- Typically hand-made, dictionaries rarely computerized, grammars never
- Not usable directly for MT or MI
- But indispensable resources
..... / Specific to MT but neutral
- Ex: MU-Project, CALLIOPE, LOGOS

LEXDB + Automatic Generation of "Running" Dict.

- For Grammars: GETA's Static Grammars

All other MT Projects have only Dynamic Grammars.
..... / Specialized (System, Phase)

- Exact format required
eg. MORPH. ANAL.: Access by MORPH, .....
- Use of predefined set of codes
(Templates, .....)

## Necessity to Separate Grammars \& Diecionaries

- Not the same writers, different competences \& creation techniques
- Dictionary / Domain

Grammar / Typology
An MT or MI System is always specialized.
.... Success of Expert Systems,
Failure of General Systems ..

- Computational Side (Time) :
- Dictionary-related phase
n: length
$O(n g)$
$O(n g \log d)$

$$
\begin{cases}g: & \text { grammar } \\ \mathrm{d}: & \text { dictionary }\end{cases}
$$

- Grammar-related phase

$$
\mathrm{G}=\mathrm{g}+\mathrm{d}
$$

RARE! EARLE..... HGPSG GPSG.....

Contrary to beliefs of theorists, a lexical approach does not guarantee small grammars.

Also
Actual dictionaries proposed by XYZGs proponents are

- Very small
- Very poor (quite poorer than usual MT dictionaries)

Actual grammars proposed by same are also

- Very small
- Too "clean" (no interest for usual phenomena) See Tsujii's, Tomita's Comments.
- It is quite possible to get a grammar larger than $200 p$ (10000 lines).

Main Computational Methods
Combinatorial Methods

- Pure : Produce all solutions

CF-Grammars in the sixties
AUGM. CF-G in the sixty-fives
(\& now - METAL, .....)
U-Grammars in the eighties
("Packing" is the new word for "Factorizing", used-of course-since 1960)

- Impure : Deliver 1 or some solutions
- Filters old idea

Mel'tchuk \& Kulagina (1956)
PIAF (1970)
..... All "Sequential" approaches

- Preferences

CETA System (For Syntax)
WILKS (Preference Semantics)
GETA's Systems (Integrated in AS)

- Weights

METAL, Critique
All solutions are computed first, then some choice is effected.

## Heuristic Methods

Try not to compute all possible solutions

- Pure : Search Strategies
(Without storing of partial results)
Backtrack Methods (PROLOG, ATN, ROBRA)
Idea: The first found is the best.
- Impure : Associated to combinatorial base

ATEF (ND-Finite State + Heuristic "Functions")
Agenda + Blackboardidea
(Not yet used in MT, but ..... in MI ?)

## How to reconcile the 2 Main Trends?

- In MT, the 2 types of techniques have achieved success.
- In speech processing (recognition), the Data-Bound, Combinatorial Methods (using weights \& not preferences) seem to WIN, the "More Intelligent" to fail.
- Quite the contrapy when it comes to "Deep" understanding, or knowledge-based processes.
- To this day, it is impossible to derive automatically an efficient program from a functional (relational) specification
- No practical results of program synthesis research
- No actual use of applicative programming
..... Also, incredibly difficult to debug even toy examples
- Theoretical limitations, eg:
$I \Psi=\left\{\mathrm{x}\left|\Psi_{\mathrm{x}}\right| \Psi\right\}$ not recursively enumerable
$\rightarrow$ Computational linguists or linguistic-oriented computer scientists are not likely to discover this GRAAL
$\rightarrow$ Some procedural component (performance related?) has to be .. programmed. Just how?

## Techniques from Classical Computer Science

- Use the (static) grammars as specification
- Construct (EX NIHILO) some program (in ROBRA, GRADE, ANT, .....)
- Enrich the program with
- Normal comments explaining the relation to the specification
- Special comments, of formal nature, the invariants, at well-chosen points
- Enrich the programming language (SLLP) with run-time procedures for checking the truth value of the invariants (always, periodically .....) and take appropriate action

## Techniques from AI

- Declarative Component
- Meta-rule Component

How to solve local problems, or heuristics

- Preferences, weights, interaction with user or knowledge base
- General Strategy

At the highest level, global handling of non-determinism

- Depth / Breadth / Best First
- Development of $n$ solutions in parallel
- Freezing / Activating .....

## A Suggestion for MI

## Specialized Languages for <br> Linguistic Programming

## Outline of Presentations

1. 3 Possible Criteria for Classifying SLLPs

- Types of Production Systems
- Rule Mechanisms (Direct, P-M, Unification)
- Control \& Modular Organization

2. SLLPs of the Direct Type
3. Pattern-Matching Based SLLPs
4. Unification-Based SLLPS
5. Discussion on the place of these 3 types of SLLPs in machine interpretation.

3 Possible Criteria for Classifying SLLPs

- Types of Production Systems

Addition - Usually followed by cleaning-up
One Structure

ex: Q-Systems, Chart Parsers

Substitution

ex: Editors (Substitute / <s1>/<s2>/)
Transformational Systems
TRANSFO, ROBRA, GRADE

Transduction

- Rule Mechanisms

Direct:
No global search in the working structure(s)
(1) Anchor

ex: Finite-state transducer (ATEF)

If variables appear, they are merely instantiaded also: Context-Free Parsers, ATNs

Pattern-Matching : LHS with variables global search But structure has no variables

Unification : Variables on both side ex: Logic Grammars (MG, DCG, XG/LMT .....) "Unification-Based" (F-Structure Based) Grammars

- Control \& Modular Organization
- Subgrammars
- Programmed

Grammars cf. Salomaa
Matrix

- Q-Systems
- ATNs, REZO
$A \rightarrow a_{1}\left|\alpha_{2}\right| \ldots \ldots \mid a_{n}$
- ATEF, ROBRA, GRADE
r: $A \rightarrow a / G 1 / G 2$

$$
\left[r^{1}, r^{3}, r^{10}\right]
$$

Simple block of rules

In reality, no subgrammars a (sub)network corresponds to all rules with same L.H.S.

Real subgrammar organisation

- Control Graph / Control Language

| ROBRA, GRADE | on Strings <br> in NLP |
| :--- | :--- |
| Validations / Saturations |  |
| (CETA) |  |

Q-Systems:
Sequence (MTL)

Trial \& Error (Prague)

- Levels of Rules

METAL (with CFG)

For Machine Interpretation,
The Main Criterion is Time Complexity
( $\sim$ Real-Time Constraint)

Hence Study by the Rule-Mechanism Classification

## SLLIPs of the Direct Type

(No global search for a pattern, essentially data-driven)

- Regular (L-R) String Transducers, even if non deterministic.
ex. ATEF
(ND)
Morphological Analysis
SYGMOR
(D)
—— Generation
- All CF-based formalisms, equipped with reasonable algorithms, if the computation does not entail matching / unification on unbounded structures

METAL, PNLP (IBM YTH)
ATN, REZO

- Tree-Transformational Systems, if in "Anchored" mode ex. TTEDIT (CETA)

## Pattern-Matching Based SLLPs

Global search for a pattern over an entire "Object Structure"

- Tree-Transformational Systems ROBRA, GRADE, TELESI (Chanché)
$\rightarrow$ Because they use substitution, they must solve conflicts

- Q-Systems

Not like chart parsers because:

- May create new nodes

- Don't test for equality

These systems are extremely powerful, \& usable not only in analysis, but in transfer \& generation

Cost: $\sim 50$ times cost of direct SLLPs
(If programmed comparably and if linguistic data comparable)

## Unification-Based SLLP's

All those where unification of potentially unbounded structures is the main operation.

- CF-Based

ex. DCG, depending on how they are used!
Not GPSG, - Where the F-structures are bounded, with no reentrancy
- \& where the result is really a complete attributed tree.
\& apparently also notJPSG (Gunji)
- MG (Metamorphosis Grammars based on CSG)
- STCG (or "Static Grammars") - Zaharin Here, identification rather than unification (Variable on 1 side may not be substituted)

## Cost of U-Based SLLPs?

- In the previous sense:

Not yet any actual measurement, on complete systems
As opposed to direct \& PM-based
Preliminary experiments $\rightarrow$ Staggering cost

Theoretical complexity
(Book by Barton, Berwick \& Ristad)
NP-complete or more
But, in practice,
Although some formalisms claim to be theories, thus exposing themselves to this reproach,

All reduce to tools, hence SLLPs
$\rightarrow$ eg. D-PATR from many U-formalisms
The real problems are:

- The cost of the used unification (Real / Pseudo)
- The added cost if types and other operations are allowed, which is necessary for a SLLP to be useful (numbers, strings, ..... intersection, difference .....)

## Discussion on the place of these 3 types of SLLP in MI

- Recall the considered levels \& scope

| Real-world, pragmatics | Whole situation, not only one <br> dialogue | $\infty$ |
| :--- | :--- | ---: |
| Dialogue dynamics <br> (in planning / understanding) | One dialogue | $<2000$ |
| Dialogue semantics  <br> (speech acts, participants) Dialogue "Window" <br> or total dialogue  | $<100$ |  |
| Utterance semantics | Utterance + Window | $?$ |
| Utterance (abstract) structure <br> (complex construction) | Utterance <br> (1-n Sentences) | $<200$ |
| Complex syntagmatic groups | Sentence at most | $<80 ?$ |
| Simple syntagmatic groups | No recursive embedding | $<15 ?$ |

Elementary syntagmatic groups
Kernels
$<5 ?$
eg. John Smith
Finite State

Words
[Syllables]
$1 \mathrm{w}=8 \mathrm{f}=400 \mathrm{~ms}$
[Pphonemes]
Signal "Frames"
$1 \mathrm{f}=50 \mathrm{~ms}$

## Real-World, Pragmatics

Dialogue Dynamics

Dialogue Semantics

Utterance Semantics

How could one "Mix" these different types?
Idea: Unify the SYNTAX (of the SLLPs)
Equip with several "Rule Engines"
Unify the Data Structures
Data Structures
There should be
Nodes with Label, \{Attributes\}, [F-Structure]

Trees (ordered)
(Loopfree) Graphs
Charts?
Q-Graphs?
Lattices?

On the Representation Trees

1) First construct only
$\square$ \{-] Skeleton
eg. by attached transformations
2) Then make the selected representation(s) more explicit by computing the F-STRUCT
3) Suppose weights have been used in the construction.

We get a natural way to translate the "Important" parts (of TSUJII) at a higher level than the rest.

Result of $1+2$
3: PRVNE

Note: "Important" does not mean "domain-related" any more, just dependent on ..... How good we judge our analysis.

Note: Translation at linguistic level does not have to be as bad (word for word) as in TSUJII's sketch!

## Lattices rather than Q-Graph or Charts?

RECALL

Lattices produce less "Parasites" when duplication is avoided

Lattices seem more used in speech processing.

# Organization of the Whole MT / MI System 

## Outline of Presentations

I. The Importance of Size

- Quantum Leaps in Methods
- Size \& Time Complexities
- Mockups, Prototypes, Operational Systems
II. Environments
- Preparation : Lingware Versions, Tests Test Corpuses
- Experimentation : Compiled Packages, Measures Validation Corpuses
- Debugging : Variety of Levels, Tools
- Production : End-User Interface Translation Request, Revision .....
III. Some Useful Concepts for Modularity
- Lingware : Steps, Phases, Components, Versions, .....
- Texts : Corpuses, Transcriptions, Translations, .....

## The Importance of Size

- Quantum Leaps in Methods

What works on small, closed problems is usually not extendable.
e.g. - Morphological analysis may be unnecessary if you work on 20 sentences.

- Trigram methods may work for 1000 words ( $10^{9}$ ELTS), unlikely for 100,000 ( $10^{15} \mathrm{ELTS}$ ).

Usual steps in MT development

|  |  | Man $\times$ Year | Dict. Size |
| ---: | ---: | :--- | ---: |
| 20 sentences | $(1$ page, 250 w.$)$ | $1-3 \times 1$ | 200 w. |
| 200 sentences | $(10$ pages, 2500 w.$)$ | $3-4 \times 3$ | 2000 w. |
| 2000 sentences | $(100$ pages, 25000 w.$)$ | $\sim 10 \times 3$ | 20000 w. |
| 20000 sentences | $(1000$ pages, 250000 w.$)$ | $\sim 20 \times 3$ | $\sim 100000 \mathrm{w}$. |

Problems in grammar \& dictionary management may force to abandon methods successful until a certain point.
e.g. - CF-based grammars begin to be unmanageable with a few hundred rules.

- Direct dictionary coding OK for $<10-15000 \mathrm{w}$, by then a lexical data base management becomes necessary.
- Although example of complex transfer dictionary
- Size \& Time Complexities

SLLPSs should be concise enough
Remember Charniak's description of "Paint" (half done!) on 9 pages of "Planner"

The same goes for the descriptions of units of translation

- For this reason, trees are preferred over graphs (note that any graph can be covered by trees). In any case locality is important.
- Linguistic trees should not have too many or too few nodes.

Compilation \& execution time crucial
The best formalism is useless if it takes an hour to compile a small grammar and a day to translate 10 words (eg. EUROTRA).

- Mockups, Prototypes, Operational Systems

Mockup : Only the heart (1, 2, 3 SLLPSSs)
No environment
Usually 1 language-pair \& 1 version
Limit : Something like METEO during 1st year of development at TAUM.
Prototypes
Small $\quad\left[\begin{array}{l}\text { Debugging environment } \\ \text { DB management of lingware } \\ \text { Almost nothing for the texts } \\ \text { Nothing for communication/operationa }\end{array}\right.$
e.g. - D-PATR Only 1 text per grammar Non sharable
(But D-PATR is far from a prototype environment for MT - no transfer, generation)

- LUTE?
Large \(\quad\left[\begin{array}{c}DBMS adequate for several versions, large <br>

dictionaries\end{array}\right\}\)| And lots of functions on texts |
| :--- |
| But no integration in Documentation System |
| Network |

e.g. ARIAVE $(-78,-85) \quad$ cf. COLING-82, JACL $86 / 1$ MU

Operational Systems
End-User interfaces $\left[\begin{array}{l}\text { Bilingual editor } \\ \text { Command panels } \\ \text { (Easy Dict. System) }\end{array}\right.$
e.g. SYSTRAN-Cee (+ TERMEX / MINITEL .....) LOGOS

## ATLAS (Fujitsu), PIVOT (NEC), HICAT (Hitachi), AS-TRANSAC (Toshiba)

## Environments

- The environment..... of the environment
- Dialogue language
- Dialogue style (abbreviated, long, detailed)
- Source language code
- Target language code
- Corpus name
- Trace parameters for each phase
...
- Preparation
- Editor settings for various types of
$\left\{\begin{array}{l}\text { Linguistic data (free / fixed format, .....) } \\ \text { Texts (input transcription) }\end{array}\right.$
- Automatic compilation (partial/total)
- Lists (with all possible sorting orders)
- Cross-references
- Synthetic views across files
(e.g. Produce all information for a set of lexical units) small tests
- Experimentation
- Facility for producing compiled packages (memory images), quickly loaded / executed
- Possibility to trace on one or several validation corpuses, $\pm$ selection
- Storing of intermediate results to
- Save future computation
- Modify them (tree editor, frame editor) to produce normalized test inputs for subsequent phases.
- Debugging

The facilities of the implementation language are not adequate
$\rightarrow$ Various views of the unit of translation input/output of a phase
$\rightarrow$ Various trace/step-by-step parameters
$\rightarrow$ If the units of translation are large, it is also important to easily isolate the erroneous part, in order to deduce the size of the structures produced.

- Production

Important to be able to start the translation of several brochures (say, 1 corpus per brochure \& 1 text per section / abstract) in less than 1 minute, when rushing out at the end of the day .....
$\rightarrow$ In a LAB, the production environment should offer the basic functions with which the operational system(s) will be built.
e.g. ARIANE as background for CALLIOPE

Modularity, ma jolie .....
One (ARIANE) Space

- Texts
- Linguistic Applications
- Linguistic Modules (memory images)
- (Lisp) Programs $\rightarrow$ You may prefer C or PROLOG!
- Natural On-Line Dictionaries
- System Files (e.g. Internal $\leftrightarrow$ External Names)
(e.g. Values of environment variables)
- Lexical Data-Base, from which MT Dictionaries are constructed (e.g. MORPH. ANALYSIS, GENER)
- Transcriptors (in LT)
e.g. 'Déjà là, DUPONT ?' $\rightarrow$ '*DE!1JA!2 LA!2, ** DUPONT'
- Personal files of individual user.
- Lingware

Step Analysis
Transfer
Generation
one could add
Speech recognition
Speech synthesis
Understanding
Phase Autonomous part of a step, written in 1 SLLP

$$
\begin{array}{lll}
\text { e.g. Morphological Analysis } & \text { AM } \\
& \text { Structural Analysis } & \text { AS }
\end{array}
$$

Component Element of a phase
e.g. Grammar G1, G2, .....

Dictionary D1, D2, ....
Selection of components gives possibly several realisations (G1 + D2)
Matrix Graph of components. PATH=realisation or of phases
e.g. Analysis

Structural Analysis

Precedence Graphs
for Compilation of Components

- Textware

Corpus Texts of same language, typology, domain, transcription (imagine ASCI/JIS)

Text Not only 1 file, but complex file set:
Source Text
Brute As inputted, in which format Revised Often, we have to preprocess slightly (spelling mistakes, OCR errors .....)
May be in more than 1 format, e.g. ISO $\varnothing 25$ (French Keyboard) \& SCRIPT JIS \& JTEX
CARIX \& TETHYS (implementation 30\%)
Descriptor Gives logical structure (sections, paragraphs, sentences) used to segment in units of translation

Formats Figures, Formulas, .....
(HORS-TEXTE)
Brute / Revised

| Translation | (Brute / Revised) <br> 1 for each $A+T+$ G realization |
| :--- | :--- |
|  |  |
| Intermediate <br> results | 1 for each variant of each phase |

Tools on Texts

| List of Words | On 1 or several | Texts <br> Concordances |
| :--- | :--- | :--- |

Merging / Splitting
\(\left.\begin{array}{ll}Printing \& \pm Translations <br>
\& \pm Revisions <br>

Editing \& -··· ···-···-···\end{array}\right\}\)| Problem of |
| :--- |
| synchronization |
| usually, by segments |

Morphosyntactic Search
e.g. Look for Art Adj Adj Noun
$\rightarrow$ Stochastic techniques have been used (Spirit System) successfully
See also Lancaster group.
$\rightarrow$ More powerful techniques for "Structural Search" should be reveloped.

See DEREDEC (Montreal) as first example.

- The Example of ARIANE-85

- Component"Matrices"

ATEF

ROBRA

EXAMPLE VERSIONS \{GRAM2\} $\left\{\begin{array}{l}\text { DICT1 } \\ \text { DICT2 } \\ \text { DICT4 }\end{array}\right\}$ \{TOURN\}

EXTRANS (for EXPANS/TRANSF)

DICT0 obligatory (DICT7, DICT2, DICT4) priority list, no repetition

TRACOMPL (for Transformation \& Complement of DECORATIONS)
 always 1 fik only

- Shared Development
(From Russing-French Experience)

4 Dictionaries

Nicolas

Andrzej
"Private"
Source / Target
Codes
Same Variables,
Formats (Templates)
Procedures as RF-Team
Development of Dictionaries
\& dont't forget to Backup !!!
\& Levels
In user space (DUPLG / DESTRUL COMMANDS)
Use Backup ("Fixed") user space (TRGLGVM)
And tapes ..... (TRGLGVM COMMAND)

## What else?

Many things not in ARIANE, ideas could come from various sources :

- Integrate everything under the editor / window system, as in lute, instead of calling the editor on speicific files.

Integrate indexing workbench, with
$\pm$ Lexical Data Base

+ Indexing Aids
- Access to "Natural" Dictionaries (MINITEL .....)

Reconsider the organization, to distribute 1 user space over a (physical or logical) network, with several users in parallel.

For machine interpretation
Add several forms of texts
\(\left.\begin{array}{l}FRAMES <br>
PHONEME <br>
SYLLABLE <br>

WORD (phon.\end{array}\right]\)| Lattice |
| :---: |
| or |
| Grid |
| or orth.) |

Tools for stochastic classification
Manual tagging of samples
Construction of HHM ("Learning") etc.

Finally, the structure of a whole MT System is like that of a software factory.

- A useful partition of sub-environments is by users:

|  | End-User |
| :--- | :--- |
|  | Linguist |
|  | Lexicographer |
| + | Phonologist come FIRST! |
| + | Cogniticist (!) |
|  | Computer Specialist $\quad$ Developers |
| Special functions, tools, ..... |  |

- Perhaps the execution can also be distributed on several machines (cf. HEARSAY), the environment should then take it into account from the start.
